

Overview

The cab booking application uses the Model–View–Controller architecture to divide the system into independent layers. This organization improves maintenance, flexibility, and future growth.

Model Layer (Data Layer)

The Model layer defines database structures and manages all data operations. Using Mongoose, it communicates with MongoDB to create, retrieve, modify, and remove records.

Controller Layer

The Controller receives client requests, validates input, applies business rules, interacts with the Model, and returns the required response.

View Layer (Routing Layer)

The routing layer contains API endpoints for HTTP methods such as GET, POST, PUT, and DELETE. Each route directs requests to the appropriate controller.

Benefits of MVC

This architecture separates responsibilities, improves code readability, supports scalability, encourages code reuse, enables independent testing, and allows multiple developers to work efficiently on different modules.
